

# The Interface of Simulation Modeling and Local Citizens in Two Eastern Iowa Watersheds

## Introduction

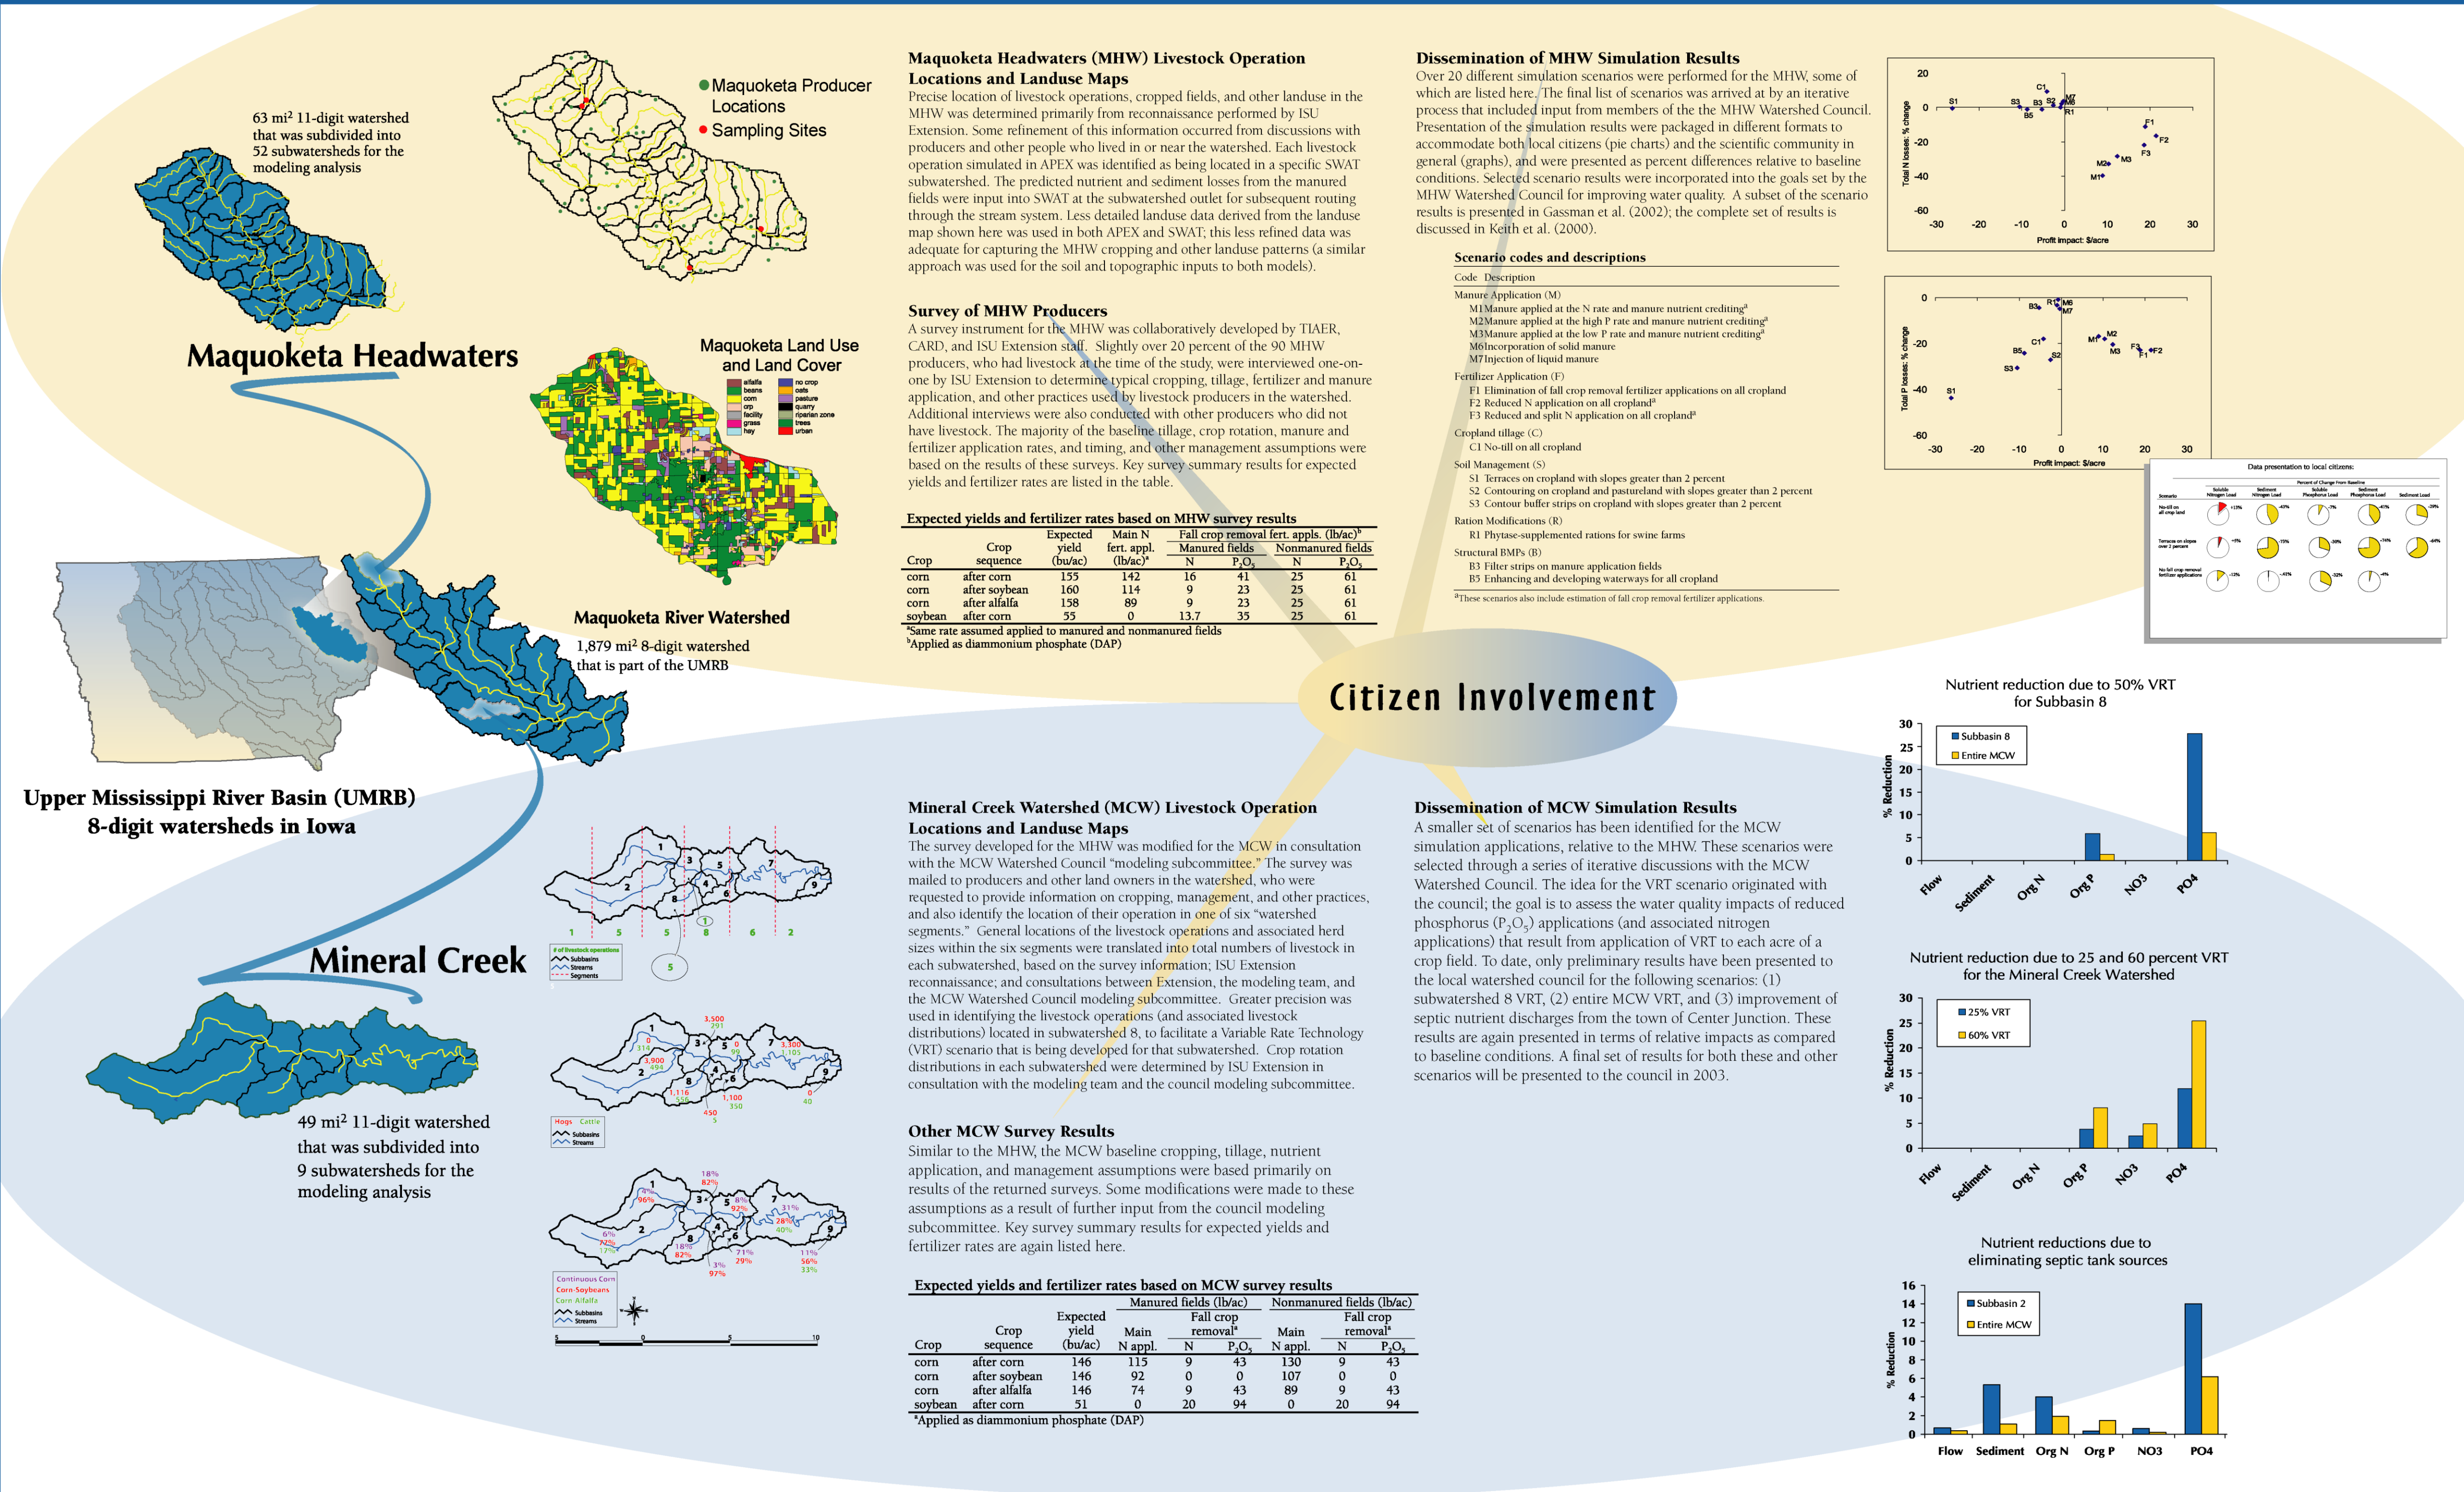

The Maquoketa River drains 1,879 square miles of predominantly agricultural land in northeastern Iowa. The 1998 Iowa Department of Natural Resources (IDNR) Unified Watershed Assessment lists the Maquoketa as a priority watershed, with the primary concern being nutrient and sediment pollutant losses from agricultural nonpoint sources. Pilot projects designed by an inter-agency task force to demonstrate new strategies for agricultural watershed protection through community-based, performance-driven environmental management have been initiated for two HUC11 subwatersheds of the Maquoketa: the Maquoketa Headwaters Watershed (MHW) and the Mineral Creek Watershed (MCW). A key component of both pilot projects is the application of an environmental and economic modeling system to provide insights into which tillage, nutrient, cropping, conservation, and other practices can provide cost effective water quality benefits. The initial application of the modeling system was performed for the MHW; a subsequent analysis is currently being conducted for the MCW. Data collection, development of model input data, and verification of model output is restricted for the MCW study due to resource constraints. Thus, to the extent possible, simulation protocols and assumptions have been transferred from the MHW to the MCW.

## Integrated Modeling System

The integrated economic and environmental modeling system consists of: (1) the Farm-level Economic Model (FEM) (Osei et al., 2000), (2) the field-level Agricultural Policy/Environmental eXtender (APEX) model (Williams et al., 1995), and (3) the watershed-level Soil and Water Assessment Tool (SWAT) model (Arnold et al., 1998). FEM is a representative farm model used to simulate farm-level economic impacts in response to different policy scenarios. APEX was developed from the Erosion Productivity Impact Calculator (EPIC) model (Williams, 1990) and is used to simulate alternative management scenarios such as variations in manure and fertilizer application rates, and adoption of structural best management practices (BMPs), for livestock operations. Edge-of-field sediment and nutrient losses simulated in APEX, coupled with losses simulated in SWAT from non-manured cropland and other land uses, are routed in SWAT through the stream system to the watershed outlet.

The integrated economic and environmental modeling system consisting of the FEM, APEX, and SWAT models.

## Conclusions

The application of the integrated economic and environmental modeling system has proven to be very robust for capturing baseline conditions and depicting alternative scenarios, for both the MHW and MCW. The involvement of local citizens has been a key aspect of the process, especially in the configuration of the models for each watershed, the selection of simulation scenarios, and review of scenario results. The analysis of the MCW is still in progress and will be completed during calendar year 2003.
