SWINE ERYSIPELAS

MANY reports from various states indicate the rapid spread of swine erysipelas at the present time.

Because of the widespread interest in this comparative newcomer among the swine diseases of this country, an informal survey on this subject was conducted among the junior and senior students at Iowa State College who had an opportunity to work with practitioners during part of August and September of this year. Answers to the various queries were given by those who had actually observed farm outbreaks of swine erysipelas. The results of the survey prove quite interesting as the students represented most sections of Iowa as well as parts of adjoining states.

A total of twenty-nine students reported observing swine erysipelas. Ninety-one separate outbreaks were listed in Iowa and surrounding states. Geographically the distribution was as follows: North, Central, and South-central Iowa; Northern and Central Illinois; Southwestern and Central Wisconsin; Southern Minnesota, and Eastern Nebraska. In Iowa, the outbreaks occurred in 17 localities; in Minnesota, four, in Illinois, four; in Wisconsin, two; and in Nebraska, two. These figures, of course, do not represent true percentage of cases in each of the areas, since most of the students worked with practitioners in Iowa.

A laboratory diagnosis confirmed the diagnosis of the practitioner in seven of the outbreaks. Most cases were diagnosed by clinical observations only. Of these, about 10 percent were given a therapeutic dose of anti-swine erysipelas serum, and the rapid improvement of the herd confirmed the tentative diagnosis. One veterinarian extensively used the agglutination test to check his diagnosis.

No definite statements concerning the number of acute and chronic cases were made. However, it was estimated that the morbidity in acute cases varied from 20 to 60 percent, and in chronic cases from 5 to 70 percent. The mortality in acute cases
